Far from the city, millions of stars are visible in the night sky. But these beautiful, twinkling lights are really giant balls of fusing gas that lie millions and millions of miles away and formed from a substance known as stardust. Stardust made the planets, too, and the Moon, comets, meteorites, and asteroids. In this absorbing book, based on the latest scientific information, young readers learn what this fundamental dust is and where its journey started. The wonders of the cosmos are beautifully depicted in Lucia

de Leiris’ s luminous illustrations.
