Adventure and discovery await in the depths of the oceans, on the Earth's varied surfaces, in the vast expanse of sky, and beyond. Advanced technologies have enabled scientists to study new species in parts of the world that were once impossible to visit.

Now, with the help of DNA testing and genetic sequencing, an astonishing 13,000 new species are identified annually. "Strange New Species takes young readers into the field with intrepid researchers as they use everything from submarines to spaghetti strainers to find wondrous new life forms. Highlights include the black-headed Sagui dwarf monkey; deep-sea tubeworms, clams, and shrimp that flourish in 800: F heat; and previously unseen microbes that survive in the oxygen-deprived mud of Mono Lake, California. Elin Kelsey's vivid text and the book's stunning photographs make this fascinating frontier of science both exciting and enlightening.
