Since the advent of the Human Genome Project, an increasing number of disease-causing genes have been discovered and, in some cases, genetic tests developed. However, this is only the first step. The second, much larger phase is the analysis of the total sequence. What does the rest of the DNA do? The answer to this question will be determined by computer prediction, expression profiling, and comparative genome analysis. This study covers such topics as identifying novel genes, and determining gene function, control sequences, and developmental switches. The book aims to demonstrate how different approaches taken with model organisms will aid in our understanding of the results coming out of the Human Genome Project and contribute significantly to our understanding of how genes function.
